Three cases of severe neurotoxicity after cobra bite (Naja kaouthia)

Alain Bernheim, Enrico Lorenzetti, Abraham Licht, Kurt Markwalder, Markus Schneemann
Department of Medicine, University Hospital, Zürich, Switzerland

Snakebites represent a health-care problem in Africa and Asia [1, 2]. In Africa, for example, snakes are responsible for hundreds of deaths each year and thousands of cases of permanent physical handicap [2].

In Switzerland, venomous snakes enjoy a growing popularity as domestic animals. For that reason the number of cases of illnesses caused by snake bites is rising [3]. We report on three patients with severe neurotoxic symptoms of poisoning after a bite by the Thai cobra Naja kaouthia (Figure 1). In 1964, an investigation of 47 patients bitten by Malayan cobra Naja naja subspecies observed the occurrence of neurotoxic symptoms in only 4 of the 47 cases [4]; whereas a study in 1986 showed 14 of 24 cases exhibited neurologic deficiencies after a bite by the Thai cobra Naja kaouthia. An ELISA test detected the presence of Naja kaouthia poison antigen in the serum of 22 of these Thai victims [5]. In both publications mentioned all patients who exhibited a local necrosis at the area of the bite wound developed signs of neurotoxicity.

Our three patients were all hospitalised as emergencies and monitored in the intensive care unit. The time interval between the snake bite and the first detectable neurologic symptoms varied from a few minutes to four hours (Table 1). All patients had a local inflammation and a swelling around the bite wound (Figure 2); laboratory findings documented an elevation of inflammatory parameters.

Patients 1 and 3 exhibited ptosis, dysphagia, dysarthria, and somnolence after four and two hours respectively. One of them had to be intubated and ventilated mechanically because of a respiratory insufficiency resulting from an increasingly shallow breathing. Patient 2 developed signs of anaphylactic shock a few minutes after the snake bite. During the transport to the hospital a cardiac arrest occurred. The patient was successfully resuscitated, intubated and ventilated mechanically. In this case (Patient 2, Table 1) it was impossible to assess how far the life threatening symptoms were neurotoxic or rather allergic, or both. The two patients who required intubation received a treatment with a Naja kaouthia specific monovalent antivenom (Thai Red Cross Society, Queen Saovabha Memorial Institute [QSMI], Bangkok).

In one case the course was complicated by a phlegmona of the hand that made surgical debridement necessary. The isolated germ was Morganella morganii, a bacterium naturally resistant to amoxycillin/clavulanic acid [6] and frequently detected in the flora of a snake’s mouth [7]. In the patient who had the anaphylactic shock at the initial phase, excitation was delayed despite regained consciousness and spontaneous breathing activity because of an extensive swelling of the tongue and the pharyngeal area. The third patient developed a deep vein thrombosis. All our patients recovered completely without further sequelae.

Conclusions

According to the course of our three cases and the recommendations documented in the literature [1], we propose the following procedure in case of a cobra bite.

Every cobra-bite incident demands hospitalisation of the victim for at least 12 to 24 hours even if poisoning symptoms are not apparent at initial presentation. The involved snake has to be identified as precisely as possible and classified with the scientific terms of the species and subspecies. Thereafter, a professional institution for the management of snake bites should be consulted to get further assistance (in Switzerland the Schweizerisches Tox-Zentrum, phone number: 041 / 251 51 51; or the Tropeninstitut Basel, phone number: 061 / 284 82 53).

If local signs occur, e.g. swelling around the bite wound, necrosis at the bite site (see Figure 2), monitoring in the intensive care unit is required and a specific antivenom should be obtained, because neurotoxicity has to be expected [4]. Any applied tourniquet or pressure dressing should be removed in a controlled manner (released by 10 mm Hg every 15 minutes) in intensive care setting only, since this procedure can provoke a dangerous systemic influx of venom. In case of neurotoxic symptoms, e.g. ptosis, dysphagia or respiratory failure, administration of a specific antivenom is required. The initial dose should amount to a minimum of 5 vials, corresponding to 50 ml of antivenom. The administration can be repeated. The use of 0.25 ml of 1:1000 adrenaline given subcutaneously immediately before the injection of antivenom serum reduces the incidence of acute adverse reactions to the serum [8]. Additional treatment with 100 mg of intravenous hydrocorti-

sone and an intravenously applied antihistaminic drug is recommended if hypersensitivity to the antivenom is expected. Prophylactic antibiotic treatment is controversial [9]. Early administration of antibiotics is probably indicated when a snake bite is located in sensitive tissues, e.g. the hand, or when oedema occurs rapidly [3]. It should cover a broad gram-positive and gram-negative aerobic and anaerobic spectrum [3], including the amoxycillin/clavulanic acid resistant germ *Morganella morganii* [6]. Thus, a combination of amoxycillin/clavulanic acid and ciprofloxacine can be suggested. Every bite wound has to be examined by an experienced surgeon because progressive swelling and necrosis may complicate the course and possibly require surgical debridement.

The many reasons why you should choose SMW to publish your research

*What Swiss Medical Weekly has to offer:*

- SMW’s impact factor has been steadily rising, to the current 1.537
- Open access to the publication via the Internet, therefore wide audience and impact
- Rapid listing in Medline
- LinkOut-button from PubMed with link to the full text website http://www.smw.ch (direct link from each SMW record in PubMed)
- No-nonsense submission – you submit a single copy of your manuscript by e-mail attachment
- Peer review based on a broad spectrum of international academic referees
- Assistance of our professional statistician for every article with statistical analyses
- Fast peer review, by e-mail exchange with the referees
- Prompt decisions based on weekly conferences of the Editorial Board
- Prompt notification on the status of your manuscript by e-mail
- Professional English copy editing
- No page charges and attractive colour offprints at no extra cost

*Editorial Board*
