To the Editor:

Stolz et al. recently presented their findings on the diagnostic value of symptoms, clinical signs and laboratory findings in lower respiratory tract infection (LRTI) in adults [1]. On admission, 243 patients with suspected LRTI were treated either as procalcitonin (PCT)-guided or by the clinical practice of the hospital, in both cases independently of the authors. After treatment two clinical subgroups were formed: bacterial LRTI (antibiotic treatment, bacterial culture positive in blood, sputum or bronchial samples, n = 52) and self-limiting LRTI (spontaneous improvement, no antibiotics, n = 86). Clinical signs and blood leukocytes (WBC) were not helpful in distinguishing between bacterial and self-limiting LRTI cases. The sensitivity of the presence of infiltrates in chest radiographs, C-reactive protein (CRP) >50 mg/L and PCT >0.1 ng/ml was 97%, 94% and 94% respectively. The likelihood ratios (LR+) were not expressed but were possible to calculate, and were 6.90 (infiltrates), 3.35 (CRP) and 3.35 (PCT). Thus, the presence of infiltrates had a significant effect (LR+ >5.0), whereas CRP >50 mg/L and PCT >0.1 ng/ml had a moderate effect (LR+ >3.0) on the pre-test probability of bacterial LRTI [2]. The authors did not investigate whether any combination of the markers managed better than single parameters.

In our recent study in 101 children with community-acquired pneumonia (CAP), bacte- rial aetiology of infection was assessed by serolog- ical methods [3]. In accordance with the results of Stolz et al. [1], clinical symptoms and signs, such as tachypnoea defined as respiratory rate >>50 breaths/min in children aged <12 months, >40 breaths/min in children aged 1–5 years and >30 breaths/min in children aged >5 years (32/81, 39%), crackles on auscultation (48/99, 48%), or fever >38 °C (22/101, 71%), >38.5 °C (18/101, 57%) or >39 °C (18/101, 38%) were not associated with bacterial aetiology. PCT, which was used to select patients for antibiotic therapy in the adult study [1], was associated with the severity of CAP like the need for hospital care and with the presence of alveolar infiltrates in the chest radiograph, but was not associated with bacterial findings in children [3, 4]. None of the non-specific laboratory parameters by any cut-off value was able to screen pneumococcal, atyp- ical bacterial and viral aetiology of infection. By the combination of CRP >100 mg/L, WBC >15000/ul, PCT >1.0 mg/ml and ESR >65 mm/h, LR+ >5.0 (sensitivity 86%, specificity 88%) in the distinction between pneumococcal and viral CAP, and 3.6 (sensitivity 41%, specificity 88%) between atypical and viral CAP. If there was a very high value in one of these four para- meters (CRP >200 mg/L, WBC >22000/ul, PCT >1.8 mg/ml or ESR >90 mm/h), LR+ for bacterial vs viral pneumonia rose to 4.8 or more, which means a significant increase from pre-test to post-test disease probability. The finding of an alveolar infiltration was associated with higher values in non-specific inflammatory markers when compared with interstitial infiltrates, but offered no additional value in the combinations.

In children the aetiological diagnosis of bacterial LRTI is even more difficult than in adults. For example, blood cultures are nearly al- ways negative, as was also seen in our study [3], the children cannot produce adequate sputum samples and invasive methods such as broncho- alveolar lavage, as used in the study of Stolz et al. [1], are justified in the most severe cases only. In our experience non-specific laboratory markers, when used as combinations, have some though a limited role in screening between bacterial and viral LRTI in children.

Key words: Streptococcus pneumoniae, lower res- piratory tract infection, community-acquired pneu- monia, procalcitonin

Authors’ reply:

We appreciate the comments of Don et al. on our study analysing the diagnostic value of signs, symptoms and laboratory parameters in an adult population admitted to hospital with lower respiratory tract infection [1]. The findings re- ported on community-acquired pneumonia (CAP) in children fit well with some of our results [2]. Interestingly, children requiring hospital admis- sion due to CAP showed higher circulating pro- calcitonin values than adult patients admitted with CAP or severe exacerbations of COPD [3, 4]. In the study by Don et al., procalcitonin was shown to adequately assess the severity of pneu- monia in children, although not capable of dif- ferentiating between bacterial and non-bacterial causes of pneumonia [5]. In this particular study, the aetiological diagnosis of pneumonia was based solely on serology in the majority of cases, reflecting the challenge of obtaining sputum and bronchoalveolar lavage samples for microbio- logical studies in paediatric patients. Thus, a pos- sible explanation for the similar procalcitonin levels in patients with positive pneumococcal, atypical bacterial, viral and unknown serology groups may be related to the methodology em- ployed. We have proposed that even patients with microbiologically proven bacterial CAP, in- cluding those with positive blood cultures, may present previous or concomitant viral infection [6]. Hence a positive virus serology alone does not preclude concomitant bacterial infection. Procalcitonin proved effective and safe in guid- ing antibiotic therapy in lower respiratory tract infection thus underlying the fact that procalci- tonin reliably identifies patients with bacterial infection requiring antibiotic therapy [3, 4, 7].

We believe that in the research setting di- rect examination of microbiological samples may not be more reliable in establishing an anti- ological diagnosis than serology only. Neverthe- less, we agree with Don et al. that a combination of a serum biomarker and a further parameter may be clinically helpful in deciding which patients have a bacterial infection. Thus, we have recently shown that serum procalcitonin or C-reactive pro- tein levels combined with need for bronchoalveolar lavage are consistently increased in immuno-compromised patients with pulmonary infections of bacterial origin [8].

The many reasons why you should choose SMW to publish your research

**What Swiss Medical Weekly has to offer:**

- SMW’s impact factor has been steadily rising. The 2006 impact factor is 1.346.
- Open access to the publication via the Internet, therefore wide audience and impact
- Rapid listing in Medline
- LinkOut-button from PubMed with link to the full text website [http://www.smw.ch](http://www.smw.ch) (direct link from each SMW record in PubMed)
- No-nonsense submission – you submit a single copy of your manuscript by e-mail attachment
- Peer review based on a broad spectrum of international academic referees
- Assistance of professional statisticians for every article with statistical analyses
- Fast peer review, by e-mail exchange with the referees
- Prompt decisions based on weekly conferences of the Editorial Board
- Professional English copy editing

**International Advisory Committee**

- Prof. K. E. Juhan Airaksinen, Turku, Finland
- Prof. Anthony Bayes de Luna, Barcelona, Spain
- Prof. Hubert E. Blum, Freiburg, Germany
- Prof. Walter E. Haeefeli, Heidelberg, Germany
- Prof. Nino Kuenzli, Los Angeles, USA
- Prof. René Lutter, Amsterdam, The Netherlands
- Prof. Claude Martin, Marseille, France
- Prof. Josef Patsch, Innsbruck, Austria
- Prof. Luigi Tavazzi, Pavia, Italy

We evaluate manuscripts of broad clinical interest from all specialities, including experimental medicine and clinical investigation.

We look forward to receiving your paper!
